1 Public Key Crypto

1.1 Que. 6

For this question I used an open source code by [1].

- For part a, run $\text{crypt}(19, 33, 3)$ and we will get $C = 28$. For decryption, run $\text{crypt}(28, 33, 7)$ and we will get the decrypted message $M = 19$. This is applicable since both encryption and decryption are exponential modulus.
- For digital signature, it is done by sign with one's private key, and verify with public key (PK). So run $\text{crypt}(25, 7, 3)$ and we will get $S = 31$. The verification is done by $\text{crypt}(31, 33, 3)$, after this, we obtain the authentic message, i.e. $M = 25$.

1.2 Que. 8

For now, researchers have discovered two kinds of cube root attack. They are [2]:

- Type 1: If the plaintext M satisfies $M < N^{\frac{1}{3}}$, then $C = M^e = M^3$. In this situation, the mod N has no effect.
- Type 2: If the same message M is encrypted with three (or more) different users' public keys, then the Chinese Remainder Theorem can be used to recover the message.

Figure 4.1: Diffie-Hellman Key Exchange

Figure 1: A Popular Key Exchange System

As a real educational example, if we use $(N, e) = (33, 3)$ and $d = 7$, when the $M = 3$, we compute $\text{crypt}(3, 33, 3)$ and get encrypted message 27. Since public key pairs are “public”, when we get the (N, e) pair, we have no trouble doing a recomputation and recover M . When $M = 4$, encrypted message is 31, greater than $N^{\frac{1}{3}}$. So if Trudy wants to recover, he has to do factoring.

1.3 Que. 11

In Diffie-Hellman (DH) Key Exchange algorithm, it is important for both sides of communication, i.e. Alice and Bob, to keep a and b as private as possible. On the other hand, the prime p and generator g are public.

1.4 Que. 12

In textbook [2], the author mentioned 3 methods to prevent man-in-the-middle attack on DH, I will illustrate encrypting with public keys. For this enhanced way, both sides will do the following stuff, assumption is that an effective network communication has or will have been set.

- Alice calculates $g^a \bmod p$ and encrypts this with Bob's one public key available.
- Alice sends the message to Bob.
- Bob calculates $g^b \bmod p$ and encrypts this with Alice's one public key available.

Figure 2: Encrypt the DH exchange with public keys

- Bob sends the message to Alice.
- Both sides decrypt the other’s message with his/her own respective private key.

Due to the assumption that Trudy has no idea of Alice and Bob’s private keys, this way works.

1.5 Que. 15

In this question, MAC stands for a less popular acronym Message Authentication Code rather than Media Access Control in the networking field. For MAC, it “uses a block cipher to ensure data integrity”. As often the case with block cipher, which is a subset of Symmetric Key Cryptography, the repudiation always exists because the *authentication and verification* use the same key. So it is fairly easy for either side of the communication to repudiate some messages.

However, as often the case in asymmetric key crptosystem, we make such assumption that the sender digitally **signs his/her message, with the private key that is *taken good care of***. In other words, only one side of the communication knows (owns) the private key, which is then used in digital signature.

1.6 Que. 16

With this question, I will have a discussion on the “entangled” relationship in everyday use of symmetric and public cryptography system.

For a hybrid system using Diffie-Hellman as public key system and DES as symmetric cipher.

- Diffie-Hellman is no more than a key exchange system. In this scenario, DH will be used to generate keys for DES, and transmit it in a DH way.
- It is obviously showed in 1. Alice sends Bob $g^a \bmod p$, and Bob sends Alice $g^b \bmod p$. The key they would use in DES then is $g^{ab} \bmod p$.
- After a shared, and to some extent secure key is constructed, the message then could easily, and more speedy (that's why we use then in reality) encrypted. After encryption, it's all about transmission, which we will not discuss for now.

For a hybrid crypto system using RSA as the public key system and AES as symmetric cipher.

- It is fairly easy to conclude that once the RSA is not used to “encrypt” something, then its task would be to digitally sign something. A digital signature is like a handwritten signature—only more so. Bob is the only one who can digitally sign as Bob, since he is the only one with access to his private key.
- As described, Bob generates a symmetric key for AES encryption, and digitally sign his AES key with his RSA private key. After doing these, Bob sends Alice the encrypted message, as well as a key signed by himself.
- Alice uses Bob's public key, which she may already have, or obtain from a public key infrastructure. If and only if Alice finds the key is truly signed by Bob, she will start decrypting messages using the (signed) key.

1.7 Que. 22

It's a very textbook question. As with the public key (18, 30, 7, 26), I wrote a MATLAB program. The answer is as follows.

- Run *SimpleKnapsack* and we will get private key, (14, 39, 42, 15).
- In the output, another hint we find is ciphertext 74 as in decimal.

1.8 Que. 26

The discussion is given below.

- When $g = 1$, it would become meaningless. For one thing, no matter what value a takes, $g^a \equiv 1$. Moreover, it is known to all that $1 \bmod p \equiv 1$ no matter what value p takes. In short, the key Alice and Bob exchange would always be 1.
- If g takes the value $p - 1$, since p and $p - 1$ are relative prime, according to Euler's Theorem, we can easily find that no matter what value a takes, $(p - 1)^a \bmod p \equiv 1$. Therefore, it's unsafe as with the scenario discussed above. It's allowable on condition that we do not consider security as an issue. 

2 Hash Functions++

In this section, we solve some hash problems.

2.1 Que. 3

Here is a short description of how brute force attack may be conducted.

- Case 1: Suppose Trudy does not have a database which stores pre-computed entries of each and every hash value of this hash function.
- Trudy has to hash each and every possible values, and compare with the target hash value, let's say T_{hash} . The total computational complexity would be $O(hashing) + O(comparing)$. (which varies according to hashing complexity, therefore non-linear.)
- Case 2: Suppose Trudy already has a hashing value database, then all he has to do is to compare n times. The computational complexity is $O(n)$.

2.2 Que. 4

The essence of hashing is mapping [3]. When keeping this in mind, the explanation would come easily.

Offset (h)	00	01	02	03	04	05	06	07	08	09	0A	0B	0C	0D	0E	0F

Figure 3: Tagged Differences Between Two Hex Files

- Since the output would be 12-bit, it can hold as many as 2^{12} , namely 4096 completely different messages. So we do **not expect collision.**
- The formula would be: *Number of collision* = 2^{m-n} .

2.3 Que. 24

I have enlisted my detailed results in *HashResults.txt*. Please refer to that file for more information. Below I take some screen shots

2.4 Que. 42

Mom told me a picture worths a thousand words. Thereafter, the pictures below will do.

2.5 Que. 48

In this explanation we discuss the usage of random numbers in cryptography.

Figure 10: Thank God It's Midterm!

- As testified by the textbook [2] and some related RFCs, in symmetric key crypto, random numbers are used to generate key pairs. Take DES as an example, pseudo random numbers are generated via S-box.
- In RSA, it is vital that the two prime numbers are as large and random as possible. So random number generator comes to rescue. Case is similar with Diffie-Hellman key exchange algorithm, where the secret exponents, i.e. the a and b in $g^a \bmod p$, $g^b \bmod p$ are generated pseudo randomly.
